ABSTRACT

Satisfiability degree is the resource of demonstrating uncertainty. It figures out whether the scope of propositional formula be true. Present algorithm calculates the satisfiability degree overlooking the dependency among propositional atoms. we simplify the calculations by using the current algorithm if there is dependencies. Dependency matrix is used to characterize the dependencies. The truth indicator stage of algorithm enumerate the satisfiability degree of a propositional formula. The unproved result shows more efficiency if there is excess dependency among the atoms.

Introduction-

As we know the satisfactory degree adjudge the propositional formula. This decision problem is of central importance in various areas, fields like computer science, circuit design[1], artificial intelligence [2].

Boolean satisfiability problem requires particular and special structure for computing. the two of them are: HORN CLAUSE & COJUNCTIVE NORMAL FORM(CNF)[3]. Horn clause is if it contains more than one positive literals[4]. CNF is if it has conjunction of clauses[5].

Many algorithm comes under CNF which is used to compute satisfiability degree eg: XOBDD algorithm[6], backtracking algorithm[7], proposition matrix search algorithm (PMSA)[8].

The output of PSMA is in matrix form as the dependencies are taken in matrix form in existing algorithm. The proposed dependency propositional matrix search algorithm computes frequency, and chooses the frequency which have maximum value. The advantage over PSMA is DPSMA (dependency propositional search matrix algorithm) as it simplifies the complexity over each iteration and then returns true or false.

DEPENDENCY MATRIX-

1: Let α be a formula which is in Prime Conjunctive Normal Form (PCNF) and q_1, q_2, \dots, q_n are propositional atoms. let $S_\alpha = \{q_1, q_2, \dots, q_n\}$ be a spanning set of formula α . The formula α is given as below.

$\alpha = c_1 \wedge c_2 \wedge \dots \wedge c_m$ Where c_1, c_2, \dots, c_m are disjunctive clauses and $m \leq 2n$. Here $D_i = p_1 \vee p_2 \vee \dots \vee p_n$ and $p_j \in \{q_j, \neg q_j\}$, $1 \leq i \leq n, 1 \leq j \leq m$.

2: As α in PCNF, the satisfiability degree is defined as a function g shown below:

$$g(\alpha) = (2n - c) / 2n$$

Where α is the number of the s clauses of formula α . In the proposed algorithm, before finding the satisfiability degree of α , proposition matrix is simplified based on the dependencies between the atoms given in the matrix.

3: Let formula $\alpha = s_1 \wedge s_2 \wedge \dots \wedge s_m$ in CNF and $S_\alpha = \{q_1, q_2, \dots, q_n\}$ be a spanning set. The proposition matrix of α , P_α have the elements based on following criteria:

- 1) $P_\alpha(i, j) = 1$, $1 \leq i \leq m, 1 \leq j \leq n$, denoting q_j appears in clause i ;
- 2) $P_\alpha(i, j) = -1$, $1 \leq i \leq m, 1 \leq j \leq n$, denoting q_j appears in clause C_i ;
- 3) $P_\alpha(i, j) = 0$, $1 \leq i \leq m, 1 \leq j \leq n$, denoting both q_j and $\neg q_j$ doesn't appear in clause C_i .
- 4) Given a formula $\alpha = s_1 \wedge s_2 \wedge \dots \wedge s_m$ in conjunctive normal form(CNF). If proposition o has nothing to do with the truth value of formula α , then o is called a free proposition.

Let $W = \{o \mid o \text{ is a free proposition}\}$ called a free set of α . If proposition o is true, formula α can be simplified into a new formula $\alpha + o$ and a free set $W + o$.

- 5) Given formula $\alpha = s_1 \wedge s_2 \wedge \dots \wedge s_m$ in CNF and its proposition matrix P_α , the high-frequency proposition q_j on the column can be calculated by using the formula. $X_i = \sum_{j=1}^n |P_\alpha(j, i)|$ where X_i indicates the frequency of q_j appearing in α .
- 6) The formula $\alpha = s_1 \wedge s_2 \wedge \dots \wedge s_m$ in conjunctive normal form(CNF) and its proposition matrix . The truth detector finds the sum of row P_α by using the following formula.

$R_k = \sum_{i=1}^m |P_\alpha(k, i)|$ $1 \leq k \leq m$ If there exists any row with $R_k = 1$, the truth detector chooses the corresponding proposition.

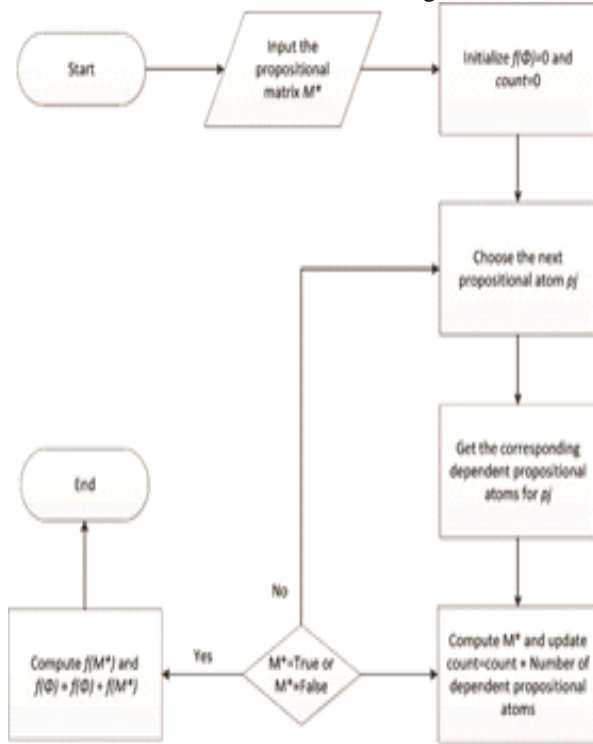

- 7) Consider a formula $\alpha = s_1 \wedge s_2 \wedge \dots \wedge s_m$ in CNF and $S_\alpha = \{q_1, q_2, \dots, q_n\}$ be a spanning set. The propositional atoms in α may consist of dependencies between them. Proposed algorithm considers the dependency between the propositional atoms in the form of provable equivalence. The dependency matrix of α , T_α have the elements based on following criteria:

- 1) $T_\alpha(i, j) = 1$, if $q_i \vdash q_j$, $1 \leq i \leq n, 1 \leq j \leq n$;
- 2) $T_\alpha(i, j) = -1$, if $q_i \vdash \neg q_j$, $1 \leq i \leq n, 1 \leq j \leq n$;
- 3) $T_\alpha(i, j) = 2$, if $\neg q_i \vdash q_j$, $1 \leq i \leq n, 1 \leq j \leq n$;
- 4) $T_\alpha(i, j) = -2$, if $\neg q_i \vdash \neg q_j$, $1 \leq i \leq n, 1 \leq j \leq n$;

5) $T\alpha(i,j) = 0$, otherwise.

III. PROPOSED ALGORITHM

Dependency matrix is used by DPMSA(dependency propositional matrix search algorithm)to calculate satisfiability degree of propositional formula .The flowchart of DPMSA is as shown in Fig .

The steps of the algorithm are given below:

Step 1: Input the proposition matrix $P\alpha$. Initial *count value* = 0 and $q(\alpha) = 0$, where *count* is used to record the number of propositions that has been processed and the function $q(\alpha)$ is used to find the satisfiability degree of a given formula α . The function $q(\alpha)$ is defined by the following formula.

$$q(\alpha) = q(\alpha_j+) + q(\alpha_j-)$$

Step 2: The next proposition p_j of α should be chosen by using the truth detector. The frequency with only single non zero value should be chosen.

Step 3: to get the equivalent proposition from the matrix add all the corresponding non zero value

E.g. Consider $\alpha = (q1 \vee \neg q2) \wedge (\neg q3 \vee q4) \wedge (q2 \vee q3) \wedge p4, S\alpha = \{q1, q2, q3, q4\}, q4 \dashv\vdash \neg q1$ and chosen proposition $p4$.

Proposition Matrix,

$$P\alpha = \begin{matrix} 1 & -1 & 0 & 0 \\ 0 & 0 & -1 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{matrix}$$

Dependency Matrix,

$$D\alpha = \begin{matrix} 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{matrix}$$

Here, the simplification process considers both $q4$ and $\neg q1$ as they are provably equivalent literals. The simplified expression is $\neg q2 \wedge (q2 \vee q3)$.

Step 4: change the value $count = count + 1$ and new atom should be included in the last step.

Step 5: Compute the function l , if $N_ = True$ or $N_ = False$

Step 6: the above steps should be repeated based on the latest high-frequency proposition of the new formula $N_$. This process continues until $N_$ can be judged as true or false.

4. EXPERIMENTAL RESULTS

Many experiments were done to verify DPMSA with existing matrix search algorithm. Experiments were done twice for finding the average run time for both DPMSA & PMSA by varying the inputs/dependencies .we will take two tables .In the first table clause=10 & variable=15 this will remain constant for calculation and dependency changes ,and for the second table clause=20 & variable=10.so by performing the experiments we can notice the changes.

Clauses ×Variables ×Dependency	Average time(ms) PMSA	Average time(ms) DPMSA
12×15×0	11.1	10.8
12×15×1	11.1	10.4
12×15×2	11.1	9.6
12×15×3	11.1	8.2
12×15×4	11.1	7.5

Clauses ×Variables ×Dependency	Average time(ms) PMSA	Average time(ms) DPMSA
20×10×0	14.3	14.3
20×10×1	14.3	13.5
20×10×2	14.3	12.6
20×10×3	14.3	11.3
20×10×4	14.3	10.1

5. CONCLUSION

In this paper we have anticipated the satisfiability degree via dependency matrix which reduces the complexity of degree of satisfiability. we successfully conclude that PMSA is not as effective as DPMSA if there exists more reliance among atoms. in future we can extend the satisfiability degree to check the models,space
